ABSTRACT

Introduction

By the end of 2015, nearly 37 million people were living with HIV and 46.3% were on antiretroviral therapy. From the 90-90-90 strategy, by 2020 at a global level, 90% of all people living with HIV who will be on antiretroviral will suppress viral load. Viral load suppression protects the immune system and prevents HIV transmission at a high level. Studies have shown that people living with HIV have near normal life expectancy assuming they suppressed their viral load. Rwanda counts 3% of HIV prevalence and 9% of unsuppressed people. The aim of this study is to assess factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district.

Methods

A cross-sectional study was carried out in Nyaruguru district and involving 637 participants. Data were collected using questionnaire and medical files review. The analysis was done using STATA. P values and odd ratio at 95% confidence interval and 5% of margin error will be used to identify significant variables and factors associated with unsuppressed HIV viral load.

Results

More than half of the study participants were female (Female: 57.77% and Males: 42.23%). The prevalence of unsuppressed HIV viral load in Nyaruguru district was found to be 8.9%. Further, 88.7% declared being satisfied with the service that they receive. Male gender was associated with unsuppressed HIV viral load [Adjusted Odds Ratio [aOR = 3.02, P = 0.020]; history of clinical failure [aOR = 3.14, P = 0.034], history of treatment interruption [aOR = 8.29, P = 0.002] and perception toward the whole life treatment [aOR = 4.32, P = 0.049] were other three factors associated with unsuppressed HIV viral load.

Conclusion

Efforts to reduce transmission rate by treating HIV to suppress viral load are in place. However, among interviewed patients, 83.8% had a good treatment adherence. Some of identified factors that are associated with unsuppressed HIV viral load include being a male person, the treatment interruption, bad perception toward the whole life treatment, the clinical failure and the health providers' confidentiality. Therefore, putting more efforts on patients counseling on HIV will improve their knowledge adherence then, suppression. Further, improve the adherence and quality of service will help in having suppressed viral load.

Recommendation

The supervision from upper to lower level and IEC to people living with HIV are recommended to improve adherence and suppression rate.

Keywords: unsuppressed, HIV/AIDS, adherence, antiretroviral, suppression

DEDICATION

I dedicate this book to my wife. Dr. Omolo Jared, Nyirahabimana Jeannette, and Kinani Peace, this book is dedicated to you for your daily advices and encouragement. It is also dedicated to my two sons Lucky Himbaza Germain and Ineza Eden Gaél; you have been patient during my absence at home due to studies.

ACKNOWLEDGEMENT

My heartiest thanks are due to:

- My supervisor Ass. Prof. Aline UMUBYEYI, MD, PhD and co-supervisor Dr. Védaste NDAHINDWA, for having spent their time for me, to improve and progress positively
- My colleagues from Munini District Hospital Laboratory for their incomparable work during my absence due to studies
- FELTP team managers, for their daily effort on my progress
- RBC, for their technical and financial support during my field work
- Nyaruguru district health facility management team for allowing me to undergo this study using the data collected from interviewed people attending Nyaruguru district health facilities for the purpose of HIV treatment.

CHAPTER I. INTRODUCTION

I.1 Background

At the end of 2015, 36.7 millions of people globally, were living with HIV. Among them, 2.1 millions were new infected cases on annual basis. In that period, the antiretroviral coverage was 46.3% among all HIV infected person(1,2). The number of people accessing treatment increased with time as one of transmission prevention measures and around 18.2 millions HIV infected people were on antiretroviral in 2016 worldwide. Compared to people that had access to treatment in 2010 and 2015 (7.5 million and 15.8 million respectively), the number kept increasing (2).In 2015, the regions in the world most affected by HIV were the Eastern and the Southern Africa. All ages considered, sub-Saharan Africa was counting around 70% on itself(2–5).

Efforts were combined to decrease new infection and increase well-being of HIV infected person. Despite those measures such as “test and treat”, sensitization on male circumcision, condom use and the increase patients access on ARVs, the viral load monitoring on regular basis for people living with HIV is crucial for early reaction to non-suppressing HIV infected person(2,3,6). The early action aims to get an undetectable or suppressed viral load that at the end will result into the decrease of the HIV transmission as shown in previous studies.

There is an increase in number in people accessing anti-retroviral therapy not only to improve the life of infected person but importantly to minimize the transmission of HIV to non-infected persons. Therefore, monitoring treatment success remains the gold standard for the viral load testing and control(7).Further, unsuppressed viral load predict that either drugs are not taken correctly or there is a resistance somewhere(6).

The target 90-90-90 set by the Joint United Nations Program on HIV/AIDS in 2014 says that by 2020, 90% of people living with HIV will be aware of their status, 90% of them, will access treatment and 90% of them will be having HIV suppressed viral load (6).Moreover, the viral load monitoring coverage in 2014 was only 50%. This low coverage was due to the test cost, the availability of trained staff and limited sites due to the complexity of the testing procedures. This gap in viral load monitoring was challenging clinicians in decision making on what to do for HIV infected people when on follow-up(7,8).

A multi-country study conducted by Medicines Sans Frontiers evidenced that 30% of people to whom treatment failure was suspected, were having elevated viral load, which means that 70% might have been unnecessarily switched to the second-line regimes if no viral load test was done to confirm the treatment failure(6,9).

Even if viral load testing has been important in following up people living with HIV, above highlighted challenges have been identified worldwide in this strategy to the extent that it becomes difficult to early determine whether a person is suppressing or not where challenges are still being faced (10–12).

Studies have shown that people living with HIV have almost normal life expectancy when suppressing their viral load(13). The prevalence of HIV in Rwanda is around 3% across the country. Females are most at risk compared to males (HIV prevalence in females: 3.7% and in Males: 2.2%). Additionally, while 83% of Rwandan people live in rural zone, HIV is most prevalent in urban setting(7.1%) compared to rural setting(2.3%)(14–16).

The viral load suppression rate among people living with HIV in Rwanda has been estimated to be 9%(17,18). While unsuppressed HIV viral load is defined as having more than 200 copies of HIV nucleic acids per milliliter of blood at list after one year of treatment(19), some people still having unsuppressed HIV viral load in Nyaruguru and up to now, no study assessed factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district.

I.2. Problem statement

Studies have been conducted in Vietnam to evaluate the prevalence of unsuppressed HIV viral load and its predictors, it has been seen that 93% patients were suppressing, this was linked to the sustainability and uninterrupted ARV treatment during the first year of treatment (20). The similar study was done in South Africa and aimed in assessing factors, which may be associated with recent unsuppressed HIV1 viral load when patients are on the first line treatment. After the data analysis, they found that 85% of patients were suppressing after six months of treatment (21). Some factors have been found to be associated with unsuppressed HIV viral load in these two studies such as: intake of alcohol in first month of treatment initiation, pregnancy, mental health status, substance

abuse, weak social support, depression, medication side effects, prior ART exposure(20,21). This was also found in population based survey done in Kenya(22).

In Rwanda, even if 91% of people living with HIV are having suppressed viral load, some factors still affecting the viral load suppression so that the whole country remains with 9% of unsuppressed clients. Some of these factors were low community based support mainly in adolescents, co infection, poor nutrition, social stigma and mismanagement of opportunistic infection, poor quality of the service in term of waiting time and service delivery and irregularity in adherence. Facing these factors, some interventions were done by the government Rwanda in collaboration with partners such as implementation of treat all strategy, improving the quality of the service, counseling adherence to people living with HIV, nutrition support as well as the diagnosis of opportunistic infections. In addition to this, clinical, biological and immunological assessment is done to have an idea on the general status of the new enrolled patients so that if any health problem is identified, the intervention is early done. For adolescents, emphasizing on adolescents follow up through “All In” initiative was also done. In term of staffing, the Ministry of health has initiated clinical mentors at all district hospitals to monitor patients care in the catchment area(17,18).

Despite all efforts put in HIV management in Rwanda, unsuppressed HIV viral load is still seen across the country and in Nyaruguru in particular. The target in initiating antiretroviral therapy for people living with HIV is to suppress their viral load. However, there is no study that assessed the factors associated with unsuppressed HIV viral load in Nyaruguru district of Rwanda. This is the reason why we are carrying out this study.

I.3. Study objectives

General objective

Assessing factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district from July 2017 to June 2018.

Specific objectives

- Estimate the prevalence of unsuppressed HIV viral load among people living with HIV in Nyaruguru district
- Measure the patient satisfaction on HIV service delivery among people living with HIV in Nyaruguru district

- Identify factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district

I.4. Research questions

- What is the prevalence of unsuppressed HIV viral load among people living with HIV in Nyaruguru district?
- What is the proportion of patients satisfied with HIV services that people living with HIV receive?
- What are factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district?

1.5. Study significance

The purpose of this study was to determine the factors associated with unsuppressed HIV viral load among people living with HIV under antiretroviral treatment in Nyaruguru district. The study significance was to contribute to the improvement of viral load suppression rate among people living with HIV in Nyaruguru district through improving quality of the service and patients behavior change by highlighting factors associated with unsuppressed HIV viral load.

I.6. Organization of the thesis

This thesis is divided into six chapters:

- Introduction: this chapter gives the background, problem statement, objectives, research questions, justification of the study and the organization of the study.
- Literature review: this part is all about what is known about HIV viral load suppression
- Methodology: will give details about how results were found.
- Results: this chapter concerns findings from data used for the study
- Discussions of the results: Compares the results of this study with other research done worldwide in the same context. It also presents limitations encountered
- Conclusion and recommendations: from findings of the study, recommendations are developed
- References

CHAPTER II. LITERATURE REVIEW

II.1. Definition of key terms

Human Immuno Deficiency Virus (HIV)

HIV (Humana Immuno Deficiency Virus) is a virus, which reproduces into the living cells. When entered in someone's body, attacks and decreases the capacity of immune system. For HIV infected person, the virus can be found in blood, liquid found in human sex, and some other body fluid (23–25).

Acquired Immuno Deficiency Syndrome (AIDS)

When HIV is introduced in someone's body, it slowly damages the capacity of the immune system in fighting against infectious microorganisms and the body start to be attacked by different pathogens both harmful and normal flora. As results, the infected person can start suffering from the different opportunistic diseases characterized by so many syndromes. At this stage, it is said that the HIV infected person is suffering from AIDS(23,25).

HIV Viral load

The HIV viral load is a total number of copies of HIV nucleic acid in body of someone living with HIV. It is measured as the number of copies of the virus in one milliliter of blood. This viral load measurement helps in monitoring the progress of HIV infection and the success of HIV treatment as well as the health status of people living with HIV(23,24).

Viral load suppression

The viral load suppression is used to say that someone under antiretroviral therapy, independently of any other criteria, have less than 200 copies of HIV nucleic acids per milliliter of blood at list after one year of well monitored treatment(19).

Unsuppressed HIV viral load

Unsuppressed viral load is a term used when someone is on antiretroviral therapy, independently of the age and still having more than 200 copies on HIV nucleic acid per milliliter of blood at least after one year of treatment(19).

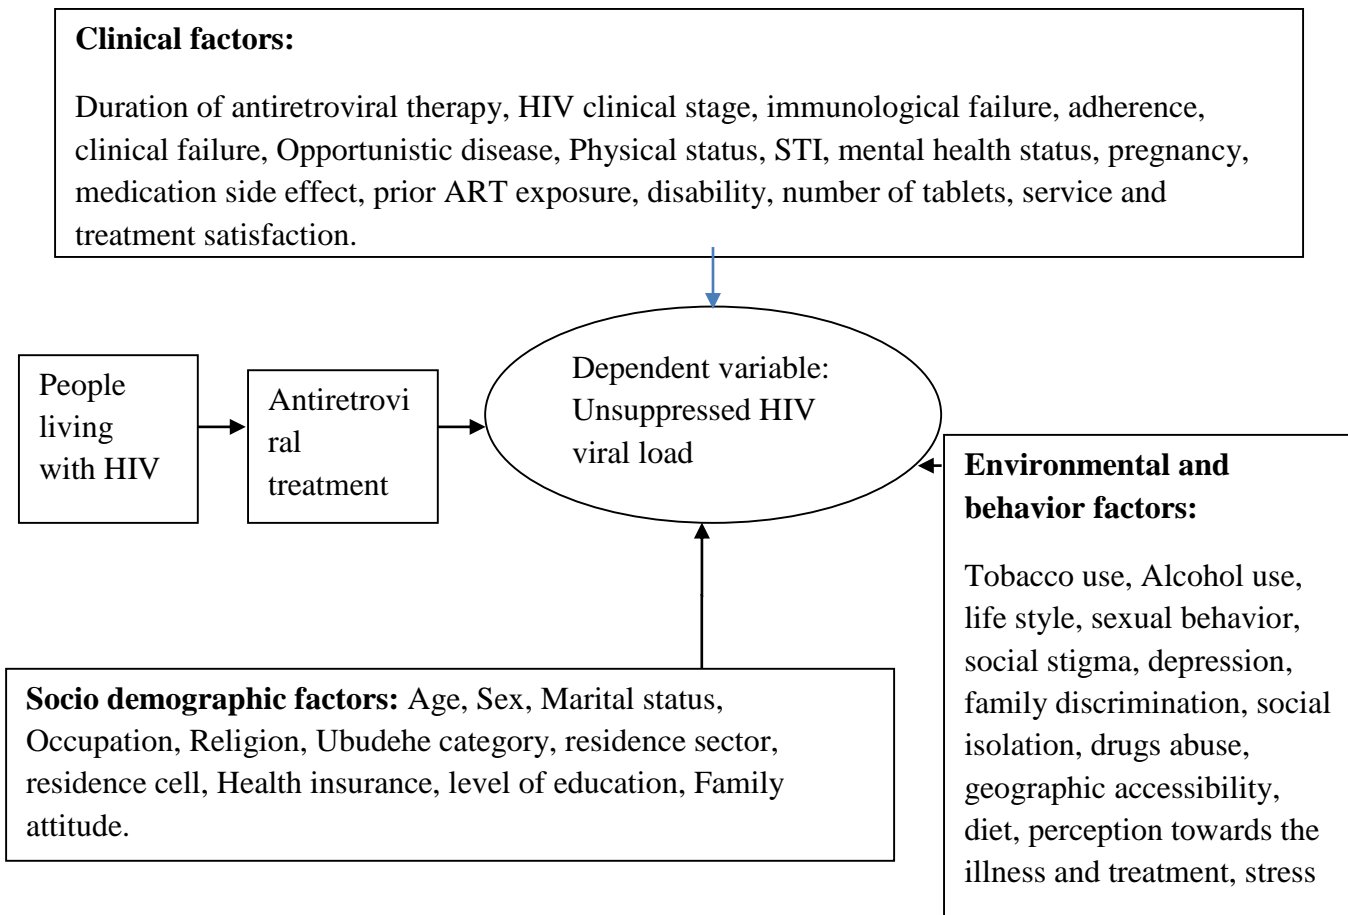

II.2. HIV patients satisfaction on service delivery

The quality of service is among elements that contribute to a good treatment adherence mainly for patients on long term treatment or whole life treatment. Among indicators of the quality of service include the confidentiality and short waiting time. It has been seen that the adherence to antiretroviral can depend on how a client is satisfied with the service delivery in relation to healthcare providers with professional guiding principles including keeping patient personal information confidential and a good treatment outcome. A study conducted in Vietnam showed that only 42.4% of patients on antiretroviral treatment were satisfied with the quality of service. In the same study, only few patients (18.8%) were satisfied with the treatment outcome(26). There is a study conducted in KwaZulu-Natal assessing the satisfaction of HIV and Tuberculosis patient on the service delivery where it has been seen that 95% of HIV patients were satisfied with healthcare services when attending the health facilities. But in some key aspect of services, this was slightly different; 16% of HIV patients reported to lack privacy when discussing with clinicians about their illness. As far as confidentiality is concerned, majority of patients (96%) reported to be comfortable with the mechanism involved in their information keeping in term of confidentiality and secret(27).

II.3. Factors associated with HIV unsuppressed viral load

The main target if initiating antiretroviral treatment is to improve someone's immune system and suppress HIV viral load. Some factors have been highlighted to negatively affect viral load suppression when someone is on antiretroviral treatment; these include the prolonged intake of alcohol in first month of treatment initiation, pregnancy, mental health disorders, substance abuse, weak social support, depression, medication side effects, prior ART exposure, stress, patients perception towards the illness and treatment, patient relationship with their clinicians, diet etc. As long as the adherence on antiretroviral is poor, the viral load will not be easily suppressed and this will affect the client well-being. As listed above, all of these factors associated with unsuppressed viral load can easily lead to poor adherence, thus, unsuppressed viral load(20,28–30).

II.4. Study conceptual framework

CHAPTER III. METHODOLOGY

III.1. Study Design

The study is a cross-sectional study. Data were collected using a developed questionnaire medical files review.

III.2. Research Setting

The study took place in Nyaruguru district. This district is one of 30 districts of Rwanda, located in the Southern province and counting 323,624 inhabitants. It is a district bordering Burundi. Further, Nyaruguru district is bordering Huye, Gisagara and Nyamagabe districts.

Nyaruguru is composed by 14 sectors where you find 16 health centers and 22 health posts. Nyaruguru district is irrigated by some of Rwanda main rivers such as Akanyaru and Mwogo. Four sectors of this district are bordering Nyungwe National Park. The whole zone of Nyaruguru district is served by Munini District Hospital that has 72 beds with full functional minimum district package. Antiretroviral therapy is provided in all Nyaruguru health facilities.

III.3. Study population

The study population was 2325 people living with HIV in Nyaruguru district, under antiretroviral therapy who were alive during our study period and who were willing to participate voluntarily in this study.

III.4. Study sample and sampling method

The prevalence of unsuppressed HIV viral load in Rwanda was 9% at the end of 2018. Based on this prevalence, the sample was calculated by using the formula below:

$$N = Z^2_{(1-\alpha/2)} \times P \times (1-P) / D$$

$$D = 2.3\%$$

$$Z_{(1-\alpha/2)} = 1.96$$

$$P = 0.09$$

Using the above prevalence, the computed minimum sample size was 579 participants to which 10% non-response or an expected missing data from medical records. Therefore, the total sample size was 637 participants. During the study period, Nyaruguru district was counting

2325 people living with HIV receiving ARV treatment for at least one year. This number was considered as study population from which the study sample was drawn. First, to know the total number of participants from each health facility to be included, the probability proportionate to size sampling technique was used as showed in the table 1:

Table 1: Sample calculation from each health facility

Health facility name	Number of eligible people	Formula used to have sample	Number of participants
Coko H C	54	$637 \times 54 / 2325$	14
Cyahinda:	310	$637 \times 310 / 2325$	83
Maraba:	43	$637 \times 43 / 2325$	11
Nyantanga:	100	$637 \times 100 / 2325$	23
Ngoma:	135	$637 \times 135 / 2325$	35
Ngera:	104	$637 \times 104 / 2325$	28
Kibeho:	204	$637 \times 204 / 2325$	55
Kabilizi:	157	$637 \times 157 / 2325$	43
Ruramba:	227	$637 \times 227 / 2325$	61
Nyamyumba:	138	$637 \times 138 / 2325$	37
Kivu:	77	$637 \times 77 / 2325$	21
Muganza:	152	$637 \times 152 / 2325$	41
Nyabimata:	121	$637 \times 121 / 2325$	33
Ruheru:	97	$637 \times 97 / 2325$	26
Runyombyi:	255	$637 \times 255 / 2325$	68
Munini HC:	41	$637 \times 41 / 2325$	11
Munini DH:	178	$637 \times 178 / 2325$	47

This number of participants above included both suppressed and unsuppressed patients. The simple random sampling method was applied at each health facility to randomly get the total number of participants. At each health facility, all patient files were labeled with numeric numbers and by using excel, they was a random selection of the numbers. After the random selection of numbers, files with selected number were picked up to be reviewed for data

collection and patients to which files were selected, were interviewed to have additional information which cannot be found in the file. The confidence interval was 95% while the study power was 80% with the margin error of 5%.

III.5. Inclusion Criteria

To be included, patient could be at least 18 years old and able to respond. To be also included in the study, the patient was asked to have at least one viral load result in the period from July 2017 up to the period of the study as well as being on antiretroviral treatment in the period from July 2016 to June 2017.

III.6. Exclusion criteria

Were excluded from the study, participants who were not accepting to voluntary participation to the study as well as those who were absent at the time of data collection.

III.7. Data collection

There was a use of close-ended question by using a developed questionnaire. Missing data was collected from the patient medical files. In addition, participants were able to answer during the interview by the use of a guided administered questionnaire.

III.8. Data analysis

Data was analyzed using STATA software, 13.0 version. Univariate analysis was done to describe the socio-demographic characteristics of the participants, prevalence of the quality of adherence as well as clinical history then after, description of behavior and level of satisfaction. Bivariate analysis was done and variables with significant P values (P value less than or equal to 0.05) were put into a logistic regression model to identify the factors associated with unsuppressed HIV viral load among study participants. P values and odd ratio were used to identify significant variables and factors associated with unsuppressed HIV viral load. In social demographic characteristics analysis, age was put into different categories with 10 as interval between groups. For some variables, the number of participants was different from the whole study participants, the reason why such variables were marked with their exception participants (N)

III.9. Variables

Dependent variable:

Unsuppressed HIV viral load

Independent variables

Socio demographic variables

Age, Sex, Marital status, Occupation, Religion, Ubudehe category, Residence sector, Residence cell, Health insurance, Level of education and Family attitude.

Before carrying out the multivariate analysis, age was grouped into three groups to maximize the chance of having any significance between age groups.

Clinical variables

Duration of antiretroviral therapy, HIV clinical stage, Immunological failure, Adherence on treatment, Clinical failure, Opportunistic disease, Physical status, Sexual transmission infection, Mental health status, Pregnancy status, Medication side effect, Prior ART exposure and Disability

Environmental and behavior factors:

Tobacco use, Alcohol use, Life style, Sexual behavior, Social stigma, Depression, Family discrimination, Social isolation, Drugs abuse, Geographic accessibility and Diet.

III.10. Ethical consideration

This study was approved by the CMHS IRB. During this study, the confidentiality in relation to patient information, data management and storage was secured. We ensured the voluntary participation in the study, all study participants have signed the consent before being involved in the study and they were allowed to leave the study at any time they wanted to. During the whole process, data was kept in secured conditions and the study participant signed voluntary participation consent.

III. 12. Study limitation

This study was conducted in Nyaruguru district and therefore not generalizable to the whole country. Additionally, the direction of association cannot be précised since this study is a cross-sectional study.

CHAPTER VI. RESULTS

IV.1. Socio-demographic characteristics of the study participants

The table below includes the description of socio-demographic characteristics of the study population. Nearly two out of three study participants was female (57.77%). Further, the majority was between 38-47 years (36.26%), 71.59% were married, 55.57 were not educated, 93.72% were having health insurance) 44.43% were in ubudehe category 3(43.43%) and 90.43 of study participants were having family members who were aware of the serologic status.

Table 2: Description of socio-demographic characteristics

Variables	Frequency (N=637)	Percentage (%)
Age group		
18-27 years	60	9.42
28-37 years	94	14.76

Awareness of family member on the participant HIV status (n=606)		
Not aware	58	9.57
Aware	548	90.43

IV.2. Prevalence of unsuppressed VIH viral load and clinical history

Among our study participants, 8.95% were having unsuppressed HIV viral load while 91.05% were suppressing, 96.89% of participants were having the same HIV status with their sexual partner, 55.26 of participants were having more than 10 years of treatment, 83.83% were having good adherence while 90.42% were not having interrupted their treatment, 94.03% were having no history of clinical failure, 78.81% were receiving 1 tablet per day, 72.21% were having no history of having opportunistic diseases, 89.95% were not having sexual transmitted disease in their history, there was no history of mental disease for 95.92% of participants, 54.89% of female participants were not having pregnancy during the treatment period, 99.69% were not been exposed to antiretroviral before becoming HIV positive, 96.08% were not having any other chronic disease, 90.89% were having no depression symptom since they are HIV positive.

Table 3: Prevalence of unsuppressed VIH viral load and clinical history

Variables	Frequency	Percentage
Suppression		
No	57	8.95
Yes	580	91.05
HIV status of the participant sexual partner (n=482)		
HIV negative	15	3.11

IV.4. Bivariate analysis of socio-demographic, behavior and environment factors

At the end of the analysis of socio-demographic, behavior and environment factors, variables was seen to be probably associated with unsuppressed HIV viral load such as age ($P = <0.001$), gender ($P = 0.013$), level of study ($P = <0.002$), awareness of family member on the participant HIV status ($P = 0.001$), history of having more than one sexual partner ($P = 0.029$), client perception towards incurable illness ($P = <0.001$), client perception towards whole life treatment ($P = <0.001$), level of satisfaction on the service delivery ($P = <0.005$), level of satisfaction on confidentiality across the whole process of treatment ($P = <0.016$). The table below shows the findings after bivariate analysis of socio-demographic, behavior and environment factors.

Table 5: Bivariate analysis of socio-demographic, behavior and environment factors

IV.5. Bivariate analysis of clinical characteristics

The analysis of clinical characteristics has shown some variables significantly associated with unsuppressed HIV viral load such as: HIV status of the participant sexual partner ($P = 0.007$), ARV treatment duration of 1 to 5 years ($P = 0.047$), history of clinical failure ($P = <0.001$), history of treatment interruption since ARV initiation ($P = <0.001$), fair quality of adherence ($P = <0.001$), poor quality of adherence ($P = <0.001$), taking 2 or 3 ARV tablets per days ($P = <0.001$), history of opportunistic disease since the HIV positivity ($P = <0.001$) and history of depression since HIV positivity ($P = <0.001$).

IV.5. Multivariable analysis

After the analysis, the following factors were significantly associated with the unsuppressed HIV viral load: gender [Adjusted Odds Ratio (aOR) = 3.02, confidence interval (CI) = 1.19 – 7.64; P value (P) = 0.020]; client perception toward the whole life treatment [aOR = 4.32, CI = 1.98 – 18.99; P = 0.049]; history of treatment interruption [aOR= 8.29, CI = 2.60 – 26.42; P = 0.002]; history of clinical failure [aOR = 3.14, CI = 1.70- 14.03; P = 0.034]; Perception toward the secret across the treatment process [aOR = 1.11, CI = 0.02- 0.53; P =0.006]. The table below shows all variables analyzed in multivariate analysis.

Table 7:Multivariate analysis of significant variables

Risk Factor	Adjusted Odds Ratio (aOR) 95% confidence interval (CI)	P values
Gender		
Female	1	0.020

No		

CHAPTER V. DISCUSSION

The current study has assessed factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district. Nearly two out of three study participants were females (57.77%) while males were 42.23%. This increased number of female is justified by the prevalence of HIV in Rwanda where HIV is more prevalent in females than in male. According to this, it is expected to have so many females living with HIV than males among HIV infected people on follow up in any health facility(31). This is comparable to the findings of Lemma Negesa et al in the study entitled “Adherence to Antiretroviral Therapy and Factors affecting among People Living with HIV/AIDS and Taking Antiretroviral Therapy, Dire Dawa Town, Eastern Ethiopia, 2017”. This Ethiopian study highlighted that 39.8% were males while and 60.2% were females(32). Even if many studies have found females to be greater than males including our study as said above, Basavaprabhu Achappa et al found 69% of males and 31% of females in the study entitled “Adherence to Antiretroviral Therapy among people living with HIV, 2016(29)”.

In this study, the prevalence of unsuppressed HIV viral load among our participants was 8.95%. This is comparable to the findings of Suresh Rangarajan *et al* in their study entitled “Factors associated with HIV viral load suppression on antiretroviral therapy in Vietnam” where 7% were not suppressing (20). But our finding slightly different from the findings of Yuriko Limmadee *et al* in their research entitled “HIV treatment outcomes following antiretroviral therapy initiation and monitoring: A workplace program in Papua, Indonesia, 2019”. They found that up to 20% were not suppressing(21). This good suppression prevalence is due to many efforts of the Rwandan Ministry of Health and Rwanda Biomedical Center in following up closely people living with HIV and by implementing the principle of ‘test and treat’ where people are tested and put on ARVs directly after being identified HIV positive(31).

We measured the patient satisfaction toward the service delivery, where we found that 88.7% were positively satisfied on the quality of the service. The satisfaction rate is good due to daily sensitization on good service delivery which is included in all level of public and private sectors to meet the customer’s need.

Male gender was associated to the unsuppressed HIV viral load [aOR= 4.61, CI = 1.66 - 12.78; P = 0.003] where males were almost five times more likely to have unsuppressed HIV viral load

compared to females. This finding corroborate with the finding of D Joseph Davey *et al* in their study entitled “Factors associated with recent unsuppressed viral load in HIV-1-infected. patients in care on first-line antiretroviral therapy in South Africa, 2018” where they found that male gender was associated with unsuppressed HIV viral load [aOR= 1.29, CI = 1.25–1.35; P = 0.001](33). This also has been found the study of Titou Hichamet *al* entitled “Risk Factors Associated with Unsuppressed Viral Load in HIV-1 Infected Patients at the First Antiretroviral Therapy in Morocco, 2019” where they found that male gender was significantly associated with unsuppressed HIV viral load (P = 0.01)(34). Due to their life style, such as alcohol consumption, sexually active, movement into or outside the country for economic issues, low level of using health services, etc, male are more likely to interrupt the treatment and final have poor adherence which can led them to have unsuppressed HIV viral load if compared to females.

ARV interruption was found to predict unsuppressed HIV viral load [aOR= 7.80, CI = 1.96 - 30.95; P = 0.003], the patients interrupting treatment were almost eight times more likely to have unsuppressed HIV viral load compared to those who are having all prescribed doses without interruption. The finding from our study was similar to the finding of Peter Cherutichet *al* in the study entitled “Detectable HIV Viral Load in Kenya: Data from a Population-Based Survey, 2016”, they found that [aOR = 2.6, CI = 1.0–7.1; P = 0.049], from this study, clients interrupting treatment were almost three times more likely to have unsuppressed HIV viral load compared to those who take all prescribed doses(35).

Reference to the good attitude toward the whole life treatment, the bad perception to the whole life treatment was significantly associated with unsuppressed HIV viral load [aOR = 0.25, CI = 0.07 - 0.89; P = 0.034]. This finding was fitting with the finding of KolabChhimet *al* in the study entitled “Factors associated with viral non-suppression among adolescents living with HIV in Cambodia: a cross-sectional study, 2018” as they found that the bad perception toward the whole life treatment was significantly associated with unsuppressed HIV viral load in adolescents [aOR = 0.40, CI = 0.21–0.75; P = 0.005]. As other drugs, ARV has their shelf life in someone’s body. Any drug interruption will decrease the synergic capacity of ARV then the virus can perform its metabolism so that new viruses are produced. When there is treatment interruption, there is more chance of inhibiting virus metabolism then increasing suppression rate.

In our study, we found that the poor quality of service such as the confidentiality was significantly associated with unsuppressed HIV viral load, [aOR = 1.11, CI= 0.02- 0.53; P =0.006]. Patients having the bad perception toward the secret keeping, were more likely to have unsuppressed HIV viral load compared to those with a good perception toward the illness secret keeping. When the patient does not believe in clinician in term of secret keeping and confidentiality, the adherence becomes poor and the motivation of attending the health facility in not good and all of these can even lead to periodic treatment interruption. This finding corroborate with the finding of Kolab Chhimet *al* in the study entitled “Factors associated with viral non-suppression among adolescents living with HIV in Cambodia: a cross-sectional study, 2018”. They found that confidentiality and disease secret is key in quality of service, so, lack of confidentiality was associated with unsuppressed HIV viral load [aOR = 2.95, CI = 1.56 – 5.99; P =0.001](30). In case of poor quality of service mainly when confidentiality is not respected, some patients will have poor adherence characterized by irregular ARV intake and as said above, this can lead to poor treatment outcome.

CHAPTER VI. CONCLUSION AND RECOMMENDATION

VI.1. Conclusion

Females were 57.77% while males were 42.23% more prevalent than males. The viral load suppression was found to be 8.95% among the study population while the satisfaction on the quality of the service was 88.7%. Given factors identified as being associated with unsuppressed HIV viral load such as Male gender, treatment interruption, whole life treatment, confidentiality in health care provider and clinical failure, improving adherence and quality of service will help in having suppressed viral load, patients continuous education is needed to sensitize on adherence so that, they will be allow level of drugs interruption which was highlighted as measure cause of unsuppressed viral load. Psychological support is also needed to be involved in patient follow up given that lack of confidentiality and negative perception toward the whole life treatment were found to be associated with unsuppressed viral load.

VI.2. Recommendation

After this study and according to the findings, some recommendations were highlighted as follow:

- ✓ The Ministry of Health through the Rwanda Biomedical Center should reinforce the regular monitoring of peripheral health facilities and try to do the regular analysis of data from those health facilities to early track some factors associated with unsuppressed HIV viral load such as irregular adherence, treatment failure, etc.
- ✓ The District Hospital supervision and HIV mentor team should early intervene at all level of the catchment area in case of irregular adherence and treatment interruption as well as any other suspected factor
- ✓ Health care providers should increase their capacity in term of secret management and good service delivery
- ✓ Information, Education and Communication (IEC) from all health care providers to people living with HIV, should insist on how to live with incurable disease and whole life treatment.

Information sheet

I am called François HAKIZAYEZU; I am a student in Masters Program, Field epidemiology and Laboratory Training Program at the University of Rwanda and I am carrying out a study entitled: **“Assessment of factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district, Rwanda, since July 2016 to June 2017”**.

There is no direct benefit from this study, but its findings will help in improving VIH management in this area in term of HIV viral load testing and results availing in timely manner so that, the follow up of people living with HIV will improve mainly when there is a need of switching on the second – line treatment regime.

The information will be gathered from the participants after filling the questionnaire. The information will include socio demographical, clinical data, environment and behavior data all related to HIV treatment regarding HIV.

In fact, the participation in this study is voluntary, mean that you are free to withdraw from the study at any time without any penalty and you are free from refusing starting with us. The information you will give through this study, will not affect you in the usual life because no participant name will be used and the whole given information will be treated confidentially. For any queries or questions, contact me through the University of Rwanda, College of Medicine and Health sciences the Chairperson of the CMHS IRB (0788 490 522) and of the Deputy Chairperson (0783 340 040), contact the supervisors of this research on 0788412644/0788454613 or use my cell phone 0788681637.

Will you please sign to your willingness to participate?

Participant’s Statement:

The study described above has been explained to me for my full understanding and I voluntarily give consent to participate in this study.

Appendix 3. Questionnaire

I am called François HAKIZAYEZU; I am a student in Masters Program, Field epidemiology and Laboratory Training Program at the University of Rwanda and I am carrying out a study entitled: **“Assessment of factors associated with unsuppressed HIV viral load among people living with HIV in Nyaruguru district, Rwanda, since July 2016 to June 2017”**.I would you to help me in having information on this study by answering the below question and this will be anonymously treated with a high level of secret and confidentiality.

Questionnaire number-----
Name of health facility-----
Participant number identification number.....

Part1:IDENTIFICATION

- 1. District of residence:
- 2. Sector:.....
- 3. Cellule:.....
- 4. Health facility of follow-up.....

Part2: SOCIO-ECONOMIC FACTORS

Gender

- 1.Male
- 2.Female

Age:.....

What is your level of study?

- 1. Non educated
- 2. Primary
- 3. Secondary
- 4. University

Have you any health insurance?

1. Yes
2. No

What is your occupation?

1. Unemployed
2. Employed
3. Private worker

What is your marital status?

1. Single
2. Married
3. Separated
4. Divorced
5. Widower

If married, have you the same HIV status with your partner?

1. Yes
2. No

If no for the question above, is your partner aware of your status?

1. Yes
2. No

If yes for the question above, is your partner have the positive attitude towards your status

1. Yes
2. No

What is your religion?.....

Which is your Ubudehe category?

1. Category 1
2. Category 2
3. Category 3
4. Category 4

Do you live with other family member?

1. Yes
2. No

Have your family members a good attitude toward your serologic status?

1. Yes
2. No

Do your family members support you in your usual life related to HIV status?

1. Yes
2. No
3. Don't know

In a typical week, how many days do you eat fruits

1. Daily
2. 1-3 days
3. 4-7 days
4. Zero days

In a typical week, how many days do you eat vegetables?

1. Daily
2. 1-3 days
3. 4-7 days
4. Zero days

In a typical week, how frequently do you eat meat?

1. Daily
2. 1-3 days
3. 4-7 days

4. Zero days

5. In a typical week, how frequently do you drink milk?

1. Daily

2. 1-3 days

3. 4-7 days

4. Zero days

Part 3: Clinical information

How long time are you on antiretroviral therapy:

1. 1 year

2. 1-5 year

3. 5-10 year

4. Above 10 years

Which is your HIV clinical stage?

1. Stage 1

2. Stage 2

3. Stage 3

4. Stage 4

Which are recent viral load results?

1. Viral load suppressed (below 200 copies)

2. Viral load unsuppressed (above 200 copies)

Have you had an immunological failure since you started treatment up to 2017?

1. Yes

2. No

Have you anytime topped treatment since you started treatment up to 2017?

1. Yes

2. No

If yes, how much time?

1. 1-10 days
2. 10-30 days
3. 1-3 months
4. 3-5 months
5. More than 5 months

If any days spent without taking drugs, which were the reasons behind

1. Severe illness
2. Medical reason
3. Drugs stock out
4. Drugs effect
5. Unknown reason
6. Believe to be cured
7. Undocumented patients transfer

Which adherence status for the clients?

1. **Poor** (Less than 85%)
2. **Good** (85% to 94%)
3. **Very good** (Above 95%)

How many number of tablet of antiretroviral to you take per day?

1. One
2. Two
3. Three
4. Four
5. More than four

Have you ever had a clinical failure?

1. Yes

2. No

Have you any physical disability avoiding you to regularly consult the health facility?

1. Yes
2. No

Have you ever had an opportunistic disease since you have been HIV positive?

1. Yes
2. No

Have you ever had a sexual transmission infection since you have been HIV positive?

1. Yes
2. No

Have you had any mental diseasesince you have been HIV positive?

1. Yes
2. No

Have you been pregnant since you started ARV until 2017?

1. Yes
2. No

Have you had any Prior ART exposure in your life before being HIV positive?

1. Yes
2. No

Have you any other chronic disease?

1. Yes
2. No

If yes to the question, which one?

1. Diabetes
2. Cancer
3. Hypertension
4. Renal failure
5. Heart failure
6. Liver failure
7. Other, specify.....

Have you ever had any depression symptom since you have been HIV positive?

1. Yes
2. No

Which among these symptoms have you had?

1. Fatigue
2. Impaired concentration
3. Insomnia
4. Hypersomnia
5. Recurring thoughts of death or suicide
6. Social isolation

Part 4:Environmental and behavior factors:

How much time do you spent to go at the health facility?

1. <30 minutes
2. 30 – 60 minutes
3. 1 – 2 hours
4. Above 2 hours

Have you ever smoked in your life?

1. Yes
2. No

If yes for the question above, for how long time?

1. Less than 5 months

2. 5-12 months
3. 1-5 years
4. 5-10 years
5. More than 10 years

Have you ever drunken alcohol in your life?

1. Yes
2. No

If yes for the above question, for how long time?

1. Less than 5 months
2. 5-12 months
3. 1-5 years
4. 5-10 years
5. More than 10 years

Have you ever hadmore than one sexual partner?

1. Yes
2. No

Have you ever had any Drugs abuse in your life?

1. Yes
2. No

If yes to the question above, for how long time?

1. Less than 5 months
2. 5-12 months
3. 1-5 years
4. 5-10 years
5. More than 10 years

What is your perception towards your illness?

1. Good
2. Bad
3. Don't know
4. Not responding

How are you satisfied with antiretroviral therapy for your whole life?

1. Good
2. Bad
3. Don't know
4. Not responding

How are you satisfied with the quality of service delivery?

1. Good
2. Bad
3. Don't know
4. Not responding

How are you satisfied with waiting time when visiting the health facility?

1. Good
2. Bad
3. Don't know
4. Not responding

How are you satisfied with the healthcare provider secret across the whole process at the health facility?

1. Good
2. Bad
3. Don't know
4. Not responding

How do you appreciate the seriousness of your clinician in term of secret?

1. Good
2. Bad
3. Don't know
4. Not responding

Thank you for your participation!!!!!!!!!!
